OBJECTIVE Although rare, frontoethmoidal meningoencephaloceles continue to pose a challenge to neurosurgeons and plastic reconstructive surgeons. Especially when faced with limited infrastructure and resources, establishing reliable and safe surgical techniques is of paramount importance. The authors present a case series in order to evaluate a previously proposed concise approach for meningoencephalocele repair, with a focus on sustainability of internationally driven surgical efforts.

METHODS Between 2001 and 2016, a total of 246 patients with frontoethmoidal meningoencephaloceles were treated using a 1-stage extracranial approach by a single surgeon in the Department of Neurosurgery of the Yangon General Hospital in Yangon, Myanmar, initially assisted by European surgeons. Outcomes and complications were evaluated.

RESULTS A total of 246 patients (138 male and 108 female) were treated. Their ages ranged from 75 days to 32 years (median 8 years). The duration of follow-up ranged between 4 weeks and 16 years (median 4 months). Eighteen patients (7.3%) showed signs of increased intracranial pressure postoperatively, and early CSF rhinorrhea was observed in 27 patients (11%), with 5 (2%) of them requiring operative dural repair. In 8 patients, a decompressive lumbar puncture was performed. There were 8 postoperative deaths (3.3%) due to meningitis. In 15 patients (6.1%), recurrent herniation of brain tissue was observed; this herniation led to blindness in 1 case. The remaining patients all showed good to very good aesthetic and functional results.

CONCLUSIONS A minimally invasive, purely extracranial approach to frontoethmoidal meningoencephalocele repair may serve well, especially in middle- and low-income countries. This case series points out how the frequently critiqued lack of sustainability in the field of humanitarian surgical missions, as well as the often-cited missing aftercare and dependence on foreign supporters, can be circumvented by meticulous training of local surgeons.

PERFORMING complex neurosurgical and plastic-reconstructive surgical procedures remains a challenging task, especially when faced with suboptimal clinical circumstances, as may be encountered in middle- and low-income countries. One condition requiring a com-

prehensive interdisciplinary approach is frontoethmoidal meningoencephalocele. A frontoethmoidal meningoencephalocele is a congenital deformity characterized by an externalization of brain tissue and meninges through a cranial bone defect (cranium bifidum) at the junction of

ABBREVIATIONS CSF = cerebrospinal fluid; NGO = nongovernmental organization.

SUBMITTED February 16, 2017. **ACCEPTED** May 8, 2017.

the frontal and ethmoidal bones, usually covered by skin. While 75% of all meningoencephaloceles are located occipitally and 10%–12% parietally, the frontoethmoidal defect occurs in 13%–15% of cases.^{1,6} Along with anencephaly and spina bifida, this malformation is one of the 3 most common neural tube defects. While its etiology and pathogenesis are still not fully understood, genetic and environmental factors, including maternal malnutrition during pregnancy and teratogenic agents, have been discussed as contributing factors.^{30,36,39,41} Frontoethmoidal meningoencephaloceles can be classified as nasofrontal, nasoethmoidal, nasoorbital, and combined types, depending on the intra- to extracranial extent of the herniated tissues. While the frontoethmoidal form is extremely rare in the Western world (incidence 1 in 35,000), it affects children in poor rural areas of lower income countries more often^{34,37} and is relatively common in Southeast Asia, with an incidence ranging from 1 in 3500 to 1 in 6000 live births.²⁵ There is a wide spectrum of clinical manifestations, ranging from symptom free to occurrence of hydrocephalus, spastic palsies, seizures, or intellectual disability. The malformation is associated with craniofacial disfigurement, functional impairment, and risk of infection of the central nervous system. Affected patients may also suffer from telecanthus,^{3,28} amblyopia, and epiphora.⁸ The typical history of the disease is progressive, with continuous herniation of intracranial contents, decreasing life expectancy drastically. Prognosis and treatment of affected patients depend on the location, size, and contents of the herniation,¹³ but in case of progressive externalization of tissue, a definitive surgical repair should be performed in infancy.⁷ A combined intra- and extracranial approach, performed within the 1st year of life in a multidisciplinary setting, remains the gold standard for such correction.^{5,14,15,19,29}

A complete extirpation of the herniated tissue is necessary to prevent further infections and deformities, or even episodes of meningitis with cerebral involvement. Unfortunately, such highly complex intracranial procedures cannot be performed safely everywhere in the world, and especially not in low-income countries with impaired health care systems and a lack of appropriate service facilities and medical personnel.

In 2008, Holm et al.¹⁶ described a series of 52 Burmese patients with frontoethmoidal meningoencephaloceles that were operated on by means of a purely extracranial approach. The surgeries were performed between 2001 and 2005 in cooperation with the local Department of Neurosurgery of Yangon General Hospital in Myanmar, and were made possible by personnel and financial support from Interplast Germany, an international nongovernmental organization (NGO) without political or religious affiliations. The chief of the Yangon General Hospital's Department of Neurosurgery (M.T.) was trained in the new technique during a visit to Austria (see *Illustrative Case 1*, below) and during 3 visits to Myanmar by the Interplast team, which included 5 of the authors (H.A., W.M., C.H.M., H.S., and P.H.) as well as German and Austrian support staff. The new technique avoids the usually necessary additional cranial opening to access the anterior fossa. Despite the difficulties regarding long-term follow-up, the authors concluded that this surgical ap-

proach was associated with low early postoperative complications and morbidity rates, while being simple, safe, and cheap.¹⁶ Since 2005, the project has been continued with only marginal financial support from Interplast. In 2012, Swiss Neurosurgeons International joined forces to boost the educational program needed to treat the population of over 50 million people living in Myanmar. Thanks to yearly educational visits to Myanmar and numerous fellowships in Switzerland for young Burmese specialists to deepen their skills and knowledge, the number of surgeons able to treat frontoethmoidal meningoencephaloceles has increased exponentially, and nationwide coverage will be reached before the end of this decade.

The goal of the present study was to evaluate whether the proposed treatment approach was in fact adopted by the local medical community, and whether it continued to prove to be a safe procedure with good outcomes in the long run. This is one of the largest series evaluating patients with frontoethmoidal meningoencephaloceles corrected by a purely extracranial approach. Furthermore, this project displays an example of how to overcome the often-discussed potential lack of sustainability in the field of medical humanitarian work, allowing the successful treatment of otherwise often-neglected patients.

Methods

Between 2001 and 2016, a total of 246 patients with frontoethmoidal meningoencephaloceles were treated using a 1-stage extracranial approach by a single surgeon in the Department of Neurosurgery of the Yangon General Hospital in Yangon, Myanmar. To allow demonstration of surgical management, 1 patient, accompanied by the senior local surgeon, was taken to Austria to undergo surgery. In the past 20 years, the Munich section of Interplast Germany has been performing 3–5 surgical missions per year in Myanmar and has developed a well-organized and widespread medical infrastructural network in the country. With the help of local trustees, affected patients were screened and registered in the different regions and brought to the former capitol city of Yangon for surgery. After the patients underwent preoperative clinical and radiographic examination (skull radiographs and CT scans), their lesions were classified using the frontoethmoidal encephalomeningocele classification according to Rojvachiranonda et al.³²

As previously described in detail,¹⁶ the procedure itself entails an extracranial approach through a vertical midline nasal incision, dissection of the meningocele up to the neck of the sac, amputation of the sac and herniated brain up to the level of the inner table of the skull, repair of the dura, bone defect closure with split-thickness calvarial bone or cartilage graft, nasal bone reconstruction, and medial canthoplasty. Local rearrangement flaps were used as needed to achieve closure.

All patients received prophylactic perioperative antibiotic treatment (ampicillin) and were kept in the hospital for 1 week after surgery. Patients were told to stay near the hospital for another 2–4 weeks before returning to their homes, which are frequently in rural areas of Myanmar. If postoperative cerebrospinal fluid (CSF) leakage occurred, bed rest was ordered and prolonged intravenous antibiotic

treatment was administered. In cases of clinical signs of elevated brain pressure, a decompressive lumbar puncture was performed. If spontaneous cessation of liquorrrhea did not occur within 2 weeks after surgery, dural repair was performed by the local neurosurgical team.

Early postoperative complications and outcomes were analyzed, and the aesthetic results were evaluated by taking into consideration anatomical features, including a long-nose deformity, telecanthus, and the position of the medial canthi.

Results

A total of 246 patients with a median age of 8 years (range 75 days to 32 years) were treated using the described approach. Nasofrontal meningoencephalocele was diagnosed in 105 cases (42.7%), nasoethmoidal in 65 (26.4%), nasoorbital in 5 (2%), and combined nasoethmoidal/nasoorbital meningoencephalocele in 71 (28.9%); 71 meningoceles (combined nasoethmoidal/nasoorbital) were bilateral. Bone defect closures with tabula externa grafts were necessary in 64 cases (26%). The duration of postoperative follow-up ranged from 4 weeks to 16 years (median 4 months).

Eighteen patients (7.3%) showed signs of increased intracranial pressure postoperatively, which was the indication for performing the placement of a ventriculoperitoneal shunt. Early CSF rhinorrhea was observed in 27 patients (11%) postoperatively, but only 5 (2%) of them required operative dural repair. In the other 22 patients, liquorrrhea resolved spontaneously under conservative therapy. In 8 patients, a decompressive lumbar puncture was performed. There were 8 postoperative deaths due to meningitis (mortality rate 3.3%). In 15 patients (6.1%), recurrent herniation of brain tissue was observed, and this unfortunately led to blindness in 1 case. Patient demographics and postoperative outcomes are summarized in Tables 1 and 2.

Illustrative Cases

Case 1

This 4-year old boy presented to the neurosurgical clinic in Yangon suffering from a large frontonasal meningoencephalocele (Fig. 1A). An interdisciplinary treatment plan was established and the patient was flown to the University Hospital Innsbruck, Austria, in the company of the senior local Myanmar surgeon so that he could participate in the operation and observe the surgical procedure and perioperative care under optimal conditions (Fig. 1B–F). Follow-up 3 and 16 years postoperatively showed an acceptable aesthetic result and full functionality (3-year follow-up photograph, Fig. 1G). The patient is fully integrated into society and creates artwork for family income (Fig. 1H).

Case 2

This 5-year-old boy presented to the clinic in Yangon with a bilateral nasoethmoidal meningoencephalocele. The surgical approach included exposure of the sac and resection of the herniated tissue. After dural repair, the defect was covered with parietal tabula externa bone grafts and closed with double advancement skin flaps. At 16

years' follow-up, the patient is socially integrated with his family, participating in traditional ox-cart racing, and has good functional and aesthetic results (Fig. 2).

Discussion

Several surgical procedures have been described to treat frontoethmoidal meningoencephaloceles, mostly based on the classic technique as described by Tessier, which includes a combined extra- and intracranial approach by means of a bicoronal incision, craniotomy, meningoencephalocele resection, creation of nasofrontal bone flaps, and facial reconstruction.^{7,9,11,21–23}

Surgery, performed in a neurosurgical center as soon as possible to avoid progression of the deformity, is the gold standard for treatment in most Western countries.^{2,11} Given the high complexity of the surgery as well as the nascent state of the health care systems and lack of advanced medical infrastructure, expedited treatment of the disease might unfortunately not always be feasible in many Asian countries, such as Burma,^{11,16} Thailand,^{2,3,10,26,38,39} Cambodia,^{9,12,33,42} Malaysia,¹ Indonesia,^{17,35} and Papua New Guinea.¹⁸ However, it has been shown that treating affected

patients under such circumstances can be made possible through the work of joint ventures between local surgeons and NGOs. To do this effectively, highly motivated local surgeons remain an indispensable resource.^{23,43} These need to be provided with continuous development opportunities, including training with visiting professionals as well as rotations at centers of excellence, with international staff and volunteers ultimately only serving in supporting roles.⁴

Regarding frontoethmoidal meningoencephalocele repair, Oucheng et al.²⁷ published a series of 200 cases that were treated by a combined neurosurgical-craniofacial approach in Cambodia and showed that good results can be achieved as long as certain surgical and perioperative principles—including clear indications, proper surgical technique, and postoperative care—are adhered to. However, they used a combined intra- and extracranial approach, which is more complex than a solely extracranial procedure. A few years later, Rifi et al.³¹ analyzed a series of 60 cases in Africa and were also able to show the feasibility of a 1-step combined procedure, elucidating the importance of repair at an early age as well as the interdisciplinary approach.

In 2008, Holm et al.¹⁶ introduced the purely extracranial approach for the correction of frontoethmoidal meningoencephaloceles and demonstrated the feasibility and safety of performing the surgery in middle- and low-income countries. While they initially encountered a relatively high incidence of postoperative CSF leaks, the technique has evolved, and leakage rates could be reduced to 11% in the current series, which is comparable to reports by other

groups (Table 3).^{11,20,24,25,27,31} This improvement might be explained by the learning curve as well as the improved availability of adequate instrumentarium and medication in Myanmar. In most patients with a postoperative CSF leak, the leakage ceased spontaneously within 2 weeks after the operation, and craniotomy and secondary dural repair became necessary in only 5 patients (2% of cases). In 8 cases (3.3%), ascending meningitis led to postoperative deaths, which might have been due, at least in part, to the suboptimal condition of perioperative hygiene in a developing country hospital. Given the constraints of the medical system, the mortality rate might be difficult to reduce much further; nonetheless, the perioperative management might be improved. Only ampicillin was used for preoperative antibiotic prophylaxis. It was the drug of choice due to its availability, broad-spectrum coverage, and low cost. However, adding sulbactam to extend coverage presents a feasible option for reducing complications. Furthermore, earlier intervention in cases of CSF leaks, which is a widely discussed topic in the literature, will be given consideration in the future. Overall, when comparing the results of this study to reports in the published literature, we found that similar incidences of early postoperative complications were observed by other groups (Table 4).^{2,3,12,20,21,24,27,28,31} In patients with intact craniofacial configuration and only minimal bone defects, this less invasive approach might provide an alternative even in high-income countries; higher-quality prospective studies would be needed to investigate this possibility further, however.

A frequent criticism of case series from low-income countries is poor follow-up. The fact that most patients are

Values presented as the number of patients (%).

living in remote areas without any established infrastructure makes it very difficult to locate patients and examine them again. In this series also, only a few patients had appropriate follow-up beyond 4–6 weeks. Overall, 15 patients came back to Yangon with recurrent herniation, and they subsequently underwent revision surgery. It is difficult to say whether the purely extracranial approach was associated with an overall higher incidence of recurrence, as has been debated by previous authors. However, the experience of the local surgeons shows that patients who encounter any problems or complications tend to come back to the place where they underwent surgery. One can thus speculate that patients who were doing well during the first 6 weeks after surgery and did not come back continued to do well, but unfortunately there is no guarantee of this, and this uncertainty regarding longer-term outcomes is a major limiting factor of the presented series.

The described approach does show, however, that even complex surgical tasks can be taught to motivated local surgeons who may subsequently continue their efforts and provide safe and efficient care to their people with only minimal additional support.

Conclusions

Frontoethmoidal meningoencephalocele repair remains a challenging surgical task. A minimally invasive purely extracranial approach may provide a useful option, especially in middle- and low-income countries with inadequate infrastructure and monetary funds. The frequently criticized lack of sustainability in the field of humanitarian surgical missions, as well as the often-cited missing aftercare and dependence on foreign supporters, could be circumvented by meticulous training of local surgeons.

Disclosures

The authors report no conflict of interest concerning the materials or methods used in this study or the findings specified in this paper.

Author Contributions

Conception and design: Heidekrueger, Broer. Acquisition of data: Heidekrueger, Thu, Schucht, K Aung, Mg Ag, Thu Soe Myint, Juran. Analysis and interpretation of data: Heidekrueger, Juran, T Aung. Drafting the article: Heidekrueger, Ehrl. Critically revising the article: Thu, Mühlbauer, Holm-Mühlbauer, Schucht, Anderl. Reviewed submitted version of manuscript: Mühlbauer, Holm-Mühlbauer, Schucht, Anderl, Schoeneich, K Aung, Mg Ag, Thu Soe Myint, Juran, T Aung, Ehrl, Ninkovic. Approved the final version of the manuscript on behalf of all authors: Heidekrueger. Statistical analysis: Heidekrueger. Administrative/technical/material support: Thu, Mühlbauer, Holm-Mühlbauer, Schucht, Anderl, Schoeneich, K Aung, Mg Ag, Thu Soe Myint, Ninkovic. Study supervision: Broer.
